

HIGH : PHP 8 Upgrade Guide

Overview

This guide walks you through upgrading your existing HIGH application from PHP 7.x to PHP 8.x safely.

This is a **framework-level update**, not a minor patch. Mistakes here will break your application if you rush.

System Requirements

Before starting, verify the following:

- PHP version: **PHP 8 to PHP 8.4**
- Required PHP extensions enabled:
 - `mysqli`
 - `mbstring`
 - `json`
 - `curl`
- Web server: Apache / Nginx
- Access to your hosting file manager or FTP

If your server is not properly configured, stop here. Upgrading code on an incompatible server is wasted effort.

Package Structure

After downloading from CodeCanyon, extract the ZIP file.

You will see:

- **Code** → Full application source
- **Documentation** → Installation guide
- **Update** → Patch files for upgrading

Fresh Installation (Skip if Upgrading)

If you are installing a new application:

1. Open [Documentation/index.html](#) in your browser
2. Follow the step-by-step installation guide

Upgrade Instructions (PHP 7.x → PHP 8.x)

Step 1: Full Backup (Non-Negotiable)

Create a complete backup of:

- Project files
- Database

If you skip this and something breaks, you will lose data. There is no safety net.

Step 2: Locate Patch Files

Go to:

Update/PHP 8 Patch/

Inside, you will find updated application files compatible with PHP 8.

Step 3: Replace Files Correctly

Upload all files and folders from the patch into your root directory.

Example:

Update/PHP 8 Patch/application → public_html/application

Rules you must follow:

- Do NOT delete existing folders manually

- Do NOT selectively copy files
- Replace **everything exactly as provided**
- Allow overwrite when prompted

Half-updates are the fastest way to break your system.

Step 4: Clear Cache & Reload

After uploading:

- Perform a hard refresh:
`Ctrl + Shift + R`
 - Clear browser cache if needed
-

Step 5: Validate the Application

Do not assume it works. Verify it.

Check:

- Login / authentication
- Forms & submissions
- Database operations
- Payment or critical flows (if applicable)

If you only check the homepage, you're setting yourself up for hidden failures.

Common Mistakes (Why Upgrades Fail)

Most issues come from these:

- Skipping backup
- Uploading files to the wrong directory
- Partial file replacement
- Running unsupported PHP version
- Ignoring PHP error logs

If something breaks, it's usually one of these—not the patch itself.

Troubleshooting

If you encounter issues:

1. Enable error reporting temporarily
2. Check server error logs
3. Re-upload patch files carefully
4. Confirm PHP version and extensions

Still stuck? Submit a support request via [CodeCanyon](#) with:

- Error message
- PHP version
